

System Availability and Maintenance

1. Overview

The unit is built for unattended outdoor operation and is designed to recover automatically from the most common problems without a site visit. It monitors its own health continuously and reports status to the secure cloud service over its own internal internet connection. No access to the client's WiFi or network is required at any time.

2. Health Monitoring and Early Warning

Regular automatic status reports sent to the cloud dashboard (heartbeat)

Active / Inactive indicator on the admin panel.

A 24-hour temperature and processing-load trend chart for spotting developing issues early.

Temperature warnings raised automatically at high thresholds.

Secure remote support: faults can be diagnosed and corrected remotely, reducing the need for site visits.

3. Data Integrity

Every event is recorded locally on the unit, independently of the network, so the on-site record is always complete.

Records are retained on the unit for 90 days; logs are managed automatically to protect storage space.

Confirmed events are also stored in the secure cloud service.

5. Recommended Maintenance

Monthly (remote, no site visit):

Confirm the unit shows ACTIVE and is reporting normally on the admin panel.

Review the 24-hour temperature/load trend (look for any upnormal temperature/load data)

Quarterly (on-site):

Inspect enclosure seals and cable entries for water ingress.

Verify the mounting and sensor orientation are undisturbed.
